SUPPLEMENTAL MATERIAL

Inclusion criteria of healthy controls and SPMS patients

Main inclusion criteria for SPMS patients were: age between 18 – 75 years, definite MS diagnosis\textsuperscript{1,2} for more than 5 years prior to enrolment, a progressive course of MS for a minimum of two years, and a moderate to heavy lesion load ($> 9$ T2 hyperintense MS-lesions) in brain MRI. Exclusion criteria were disease modifying treatment within 3 months, or corticosteroid treatment within thirty days of evaluation, EDSS score $> 8$, active neurological or autoimmune disease other than MS, or another comorbidity considered significant. The control subjects were age and sex matched healthy individuals with no known neurological symptoms or diseases. Initially, 10 healthy controls and 10 SPMS patients were enrolled in the study. One control subject (male, age 62 years) was excluded because of unexpected, multiple white matter lesions of vascular origin in the MRI, and one healthy female’s (44 years, no prior history of anxiety) $^{11}$C-PK11195 PET data was discarded because of poor image quality due to excessive head movements during the scan caused by sudden anxiety. Therefore, 8 control subjects were included in the final evaluation. In addition, one SPMS patient had a single right-sided, cortical occipital lesion consistent with an old ischemic infarction, but no other ischemic changes. Due to the volume reduction caused by the infarction, this patient was excluded from the volumetric correlational analyses. One healthy control had mild ischemic degenerative changes in the WM without consequent tissue loss or old infarctions. None of the ischemic lesions in either group were included in ROI analyses.

Methodology for obtaining conventional MR images and MR image parameters

Brain MRI with Philips Gyroscan Intera 1.5 T Nova Dual scanner (Philips, Best, the Netherlands) was performed on all subjects for neuroradiological analysis and acquisition of anatomical reference for the PET images. The MRI sequences included axial T1 and T2 weighted, coronal T2 weighted fluid attenuated inversion recovery (FLAIR), and axial Gadolinium-enhanced 3DT1 weighted series. Total lesion load of the white matter (WM) MS plaques was determined from coronal FLAIR scans using a semiautomated thresholding technique. The measurement of total brain, WM and GM volumes was performed using SIENAX (structural image evaluation, using normalisation, of atrophy - v2.6, part of FSL).

Methodology for pre-processing 3DT1 MR images for the parametric PET image analysis

The preprocessing of the 3DT1 MR images for the parametric PET image analysis was performed with Voxel-Based Morphometry, version 8 (VBM8), a toolbox in Statistical Parametric Mapping, version 8 (SPM8), running on MatLab 2011 (The MathWorks, Natick, MA). The 3DT1 MR images were first coregistered to the sum of motion corrected PET images and then segmented into WM and GM images. Additionally, the deformation fields used for spatial normalisation were calculated via high dimensional DARTEL algorithm yielding improved anatomical precision.

\textbf{\(^{11}\)C-PK11195 radioligand production}

\(^{11}\)C-PK 11195 (\((R)-[^{11}\text{C}]-N\)-methyl-\(^{11}\text{C}\)-1-(2-chlorophenyl)-\(N\)-(1-methylpropyl)-3-isoquinolinecarboxamide) was synthesized using the previously published methods\(^1,2\) with some modifications. Briefly, \(^{11}\)C-carbon dioxide was converted into \(^{11}\)C-methyl iodide, which was trapped into a solution of desmethyl-\((R)\)-PK11195 (1.0 mg) and 3.0 \(\mu\)l of 1.0 M tetrabutylammonium hydroxide in dimethyl sulfoxide (150 \(\mu\)l). Reaction mixture was heated at 80 \(^\circ\)C for 3 minutes. Tracer was subsequently purified with semipreparative HPLC. 0.5 ml of propylene glycol/ethanol (7/3) was added to the collected fraction and the fraction was evaporated. Residue was formulated in 0.1 M phosphate buffer (pH 7.4) containing propylene glycol/ethanol (8:2) and sterile filtered through Pall Corp. Acrodisc 0.2 \(\mu\)m HT Tuffryn membrane. Radiochemical purity of produced \(^{11}\)C-PK 11195 was more than 99 % and specific radioactivity was 42 \(\pm\) 11 MBq/nmol (mean\(\pm\)standard deviation) at the time of injection.
