The κ-opioid receptors (KORs) are implicated in several neuropsychiatric diseases and addictive disorders. PET with radioligands provides a means to image the KOR in vivo and investigate its function in health and disease. The purpose of this study was to develop the selective KOR antagonist 11C-LY2459989 as a PET radioligand and characterize its imaging performance in nonhuman primates. Methods: LY2459989 was synthesized and assayed for in vitro binding to opioid receptors. Ex vivo studies in rodents were conducted to assess its potential as a tracer candidate. 11C-LY2459989 was synthesized by reaction of its iodophenyl precursor with 11C-cyanide, followed by partial hydrolysis of the resulting 11C-cyanophenyl intermediate. Imaging experiments with 11C-LY2459989 were performed in rhesus monkeys with arterial input function measurement. Imaging data were analyzed with kinetic models to derive in vivo binding parameters. Results: LY2459989 is a full antagonist with high binding affinity and selectivity for KOR (0.18, 7.68, and 91.3 nM, respectively, for κ, μ, and δ receptors). Ex vivo studies in rats indicated LY2459989 as an appropriate tracer candidate with high specific binding signals and confirmed its KOR binding selectivity in vivo. 11C-LY2459989 was synthesized and characterized for in vivo specific binding signal, thus making it a promising PET imaging agent for use in humans.

Key Words: kappa opioid receptor; antagonist; PET; radioligand; synthesis and evaluation

The opioid receptors (ORs) are G-protein–coupled receptors with at least 3 subtypes: μ, κ, and δ (1). The ORs share extensive homology but differ in their pharmacology and physiologic effects (2). The presence of κ-opioid receptors (KORs) is widespread in the human brain and is found in greater density than the μ-opioid receptor (MOR) in most brain regions (3–5). KORs are present in the deep layers of cortical regions and in the striatum, hippocampus, amygdala, and thalamus (3,5,6). A similar distribution of KORs is seen in the nonhuman primate brain (7,8).

KORs are implicated in the pathophysiology of a variety of neuropsychiatric diseases and addictive disorders (9). For example, multiple lines of evidence point to the involvement of KORs in depression and related mood disorders (10–16). In turn, these findings raise the possibility that KOR antagonists might be efficacious antidepressants. As such, KORs are a target for development of newer antidepressants. In addition, the role of the opioid system in alcohol addiction and treatment is well established, as the nonselective opioid antagonist naltrexone is effective in the prevention of relapse in some alcoholics (17). There is also a large body of literature indicating that the opioid system, especially the KOR, is critically involved in the biology of addiction to psychostimulants, and thus pharmacologic intervention at the KOR/dynorphin system may be an effective avenue for treatment of drug and alcohol abuse (18).

Because KORs are involved in several psychiatric diseases and addictive disorders, the successful deployment of a PET imaging agent for use in humans will allow the noninvasive investigation of the KOR in vivo and lead to new understandings of its function and dysfunction/dysregulation in these disorders. It will also make it possible to correlate and translate preclinical findings in animal models to humans and help in the development of novel therapeutic agents by correlating dose, pharmacokinetic parameters, and receptor occupancy.

Several radiotracers are currently available for imaging the ORs in humans. They include 11C-carfentanil, 11C-3βF-diprenorphine, 11C-buprenorphine, 11C-cyclofoxy, and 11C-methyltralnirudole (19,20). None of these ligands can be used to selectively image KOR in vivo. Over the years, many groups have attempted to...
develop KOR-selective PET radioligands, such as the agonist ligands $^{11}$C-GR89696 and $^{11}$C-GR103545 and the antagonist ligand $^{11}$C-MeJDtic (Fig. 1) (21–24). However, only $^{11}$C-GR103545 has been evaluated extensively in nonhuman primates and recently in humans in our laboratory (25–28). We previously reported the synthesis of $^{11}$C-LY2795050 as the first-ever selective antagonist radioligand able to image the KOR in nonhuman primates and humans (29). In this paper, we report the discovery and characterization of $^{11}$C-LY2459989 (Fig. 1) as a KOR-selective radioligand with improved imaging characteristics over $^{11}$C-LY2795050.

MATERIALS AND METHODS

Chemistry

Synthesis of LY2459989 and the radiolabeling precursor for $^{11}$C-LY2459989 is described in the supplemental materials (available at http://jnm.snjm.org).

In Vitro Binding Assays

In vitro binding experiments and GTP-γ-S antagonist functional assays were performed according to the published procedures (30).

Ex Vivo Experiments in Rodents: Tracer Distribution and Receptor Occupancy Studies

Male Sprague–Dawley rats (225–300 g; Harlan Laboratories) were group-housed with ad libium food and water and maintained on a 12-h light–dark cycle. All experiments were conducted under protocols approved by the Institutional Animal Care and Use Committee of Eli Lilly & Co.

$^{11}$C-LY2459989 was dissolved in 25% 3-hydroxypropyl-β-cyclodextrin at a concentration of 6 μg/mL and administered intravenously via the lateral tail at a dose of 3 μg/kg to groups of rats (4 rats in each group) in a volume of 0.5 mL/kg. Animals were sacrificed at 5, 20, 40, or 60 min after LY2459989 injection. The striatum and cerebellum were dissected, weighed, and positioned in conical centrifuge tubes placed on ice. Four volumes (w/v) of acetonitrile containing 0.1% formic acid were added to each tube. These samples were then homogenized using an ultrasonic probe (7–8 watts power using a sonic probe dismembrator; Fisher Scientific) and centrifuged at 14,000 rpm for 16 min. The supernatant was separated and diluted 1:4 with sterile water in high-performance liquid chromatography (HPLC) injection vials for LC/MS/MS analysis. The chromatographic separation was performed with a Zorbax SB-C18 column (2.1 × 50 mm, 1.8 μm; Agilent) and gradient of components A (0.1% formic acid in acetonitrile) and B (0.1% formic acid in water) over 3.5 min (5% A for 1 min, then increasing to 90% A from 1 to 1.75 min and 90% A from 1.75 to 2 min, decreasing to 5% A at 2.1 min and holding until 3.5 min) at a flow rate of 0.40 mL/min. The detection of tracers was accomplished by monitoring ion transitions 414.1/343.0, 342.2/270.2, and 320.2/249.0 until 3.5 min (5% A for 1 min, then increasing to 90% A from 1 to 1.75 min and 90% A from 1.75 to 2 min, decreasing to 5% A at 2.1 min and holding until 3.5 min) at a flow rate of 0.40 mL/min. The detection of tracers was accomplished by monitoring ion transitions 414.1/343.0, 342.2/270.2, and 416.0/301.1 mass-to-charge ratio for GR103545, naltrexone, and naltrindone, respectively.

Radiochemistry

Instruments used were as follows: a preparative HPLC system including a Shimadzu LC-20A pump, a Rheodyne K200 ultraviolet detector, a Bioscan 416.0/301.1 liquid chromatography (HPLC) injection vials for LC/MS/MS analysis using a model 1200 HPLC (Agilent Technologies) system and an API 4000 mass spectrometer (Applied Biosystems). The chromatographic separation was performed using a Genesis C18 column (10 × 250 μm, Agilent) and a mobile phase gradient of acetonitrile (A) and water (B), each containing 0.1% formic acid over 5 min (5% A for 1 min, then increasing to 95% A from 1 to 2 min and holding from 2 to 3 min, decreasing to 5% A at 3.1 min and holding until 5 min), at a flow rate of 0.25 mL/min. Detection of $^{11}$C-LY2459989 was accomplished by monitoring the precursor to product ion transition with a mass-to-charge ratio (m/z) of 392.301 to 244. Standards were prepared by adding known quantities of $^{11}$C-LY2459989 to brain tissue samples from nontreated rats and processed as described above. Concentrations of $^{11}$C-LY2459989 in the striatum were presumed to represent total binding, whereas levels in the cerebellum represented nonspecific binding because this is a region with little or no expression of ORs (31). The concentration ratio between striatum and cerebellum is presented as a measure of specific binding.

Occupancies of $^{11}$C-LY2459989 at KOR, MOR, and DOR were determined using an in vivo rat model of central receptor occupancy and the procedures described previously, with GR103545, naltrexone, and naltrindone as in vivo tracers for KOR, MOR, and DOR, respectively (32). They were injected intravenously 1 h after oral administration of vehicle or $^{11}$C-LY2459989 (0.01, 0.03, 0.1, 0.3, 1, 3, 10, or 30 mg/kg). Animals were sacrificed by cervical dislocation 30 min after tracer administration. Tracer analysis was performed using a model 6460 MS/MS system equipped with a 1260 HPLC system (Agilent Technologies). The chromatographic separation was performed with a Zorbax SB-C18 column (2.1 × 50 mm, 1.8 μm; Agilent) and gradient of components A (0.1% formic acid in acetonitrile) and B (0.1% formic acid in water) over 3.5 min (5% A for 1 min, then increasing to 90% A from 1 to 1.75 min and holding from 1.75 to 2 min, decreasing to 5% A at 2.1 min and holding until 3.5 min) at a flow rate of 0.40 mL/min. The detection of tracers was accomplished by monitoring ion transitions 414.1/343.0, 342.2/270.2, and 416.0/301.1 mass-to-charge ratio for GR103545, naltrexone, and naltrindone, respectively.

Radiochemistry

Instruments used were as follows: a preparative HPLC system including a Shimadzu LC-20A pump, a Rheodyne 7133i injector with a 2-mL loop, a Knauer K200 ultraviolet detector, a Bioscan γ-flow detector, and a laptop computer running the EZStart data acquisition software and an analytic HPLC system consisting of a Shimadzu LC-20A quaternary pump, a Rheodyne 7133i injector, a Shimadzu SPD-M20A PDA or SPD-20A ultraviolet detector, a flow cell γ detector (Bioscan), and a PC with Shimadzu Class VP 7.2 software used for system control. Chiral HPLC analysis was performed with a Chiralpak AS-H column (4.6 × 150 mm) eluting with 0.2% triethylamine in MeOH at a flow rate of 0.6 mL/min.

The production of $^{13}$C-CO$_2$ was started with the $^{14}$N(p,α)$^{13}$C nuclear reaction by bombardment of a mixture of nitrogen and oxygen (0.5%–1%) with a proton beam. In a high-pressure target in a PETrace cyclotron (GE Healthcare). The cyclotron-produced $^{13}$C-CO$_2$ was transferred into a ProCab (GE Healthcare) and reacted with hydrogen at 400°C under a nickel catalyst to afford $^{13}$C-methane, which was converted to $^{13}$C-cyanide by reaction with ammonia over a platinum catalyst at 950°C. Radiolabeling was performed by trapping $^{13}$C-cyanide in a solution of precursor 6 (1–3 mg) (Fig. 2). $^{13}$C-MeJDtic, Pd$_2$(dba)$_3$, and dppf in DMF (0.3 mL) at room temperature. Reaction at 80°C for 5 min produced the intermediate $^{13}$C-7, which was then treated with NaOH (1 N, 0.2 mL) and H$_2$O$_2$ (0.2 mL) at 80°C for 5 min to afford $^{13}$C-LY2459989 ($^{13}$C-5) (Fig. 2).

Purification was achieved by preparative HPLC using a Genesis C18 column (10 × 250 μm, 5/22/14 [Fig 2] 5/22/14

![FIGURE 1. Structures of selected KOR ligands.](image-url)
PET Imaging Experiments in Rhesus Monkeys

PET Procedures. Experiments were performed in rhesus monkeys (Macaca mulatta) according to a protocol approved by the Yale University Institutional Animal Care and Use Committee and procedures as described previously (33).

Three animals were used in this study. In the first set of experiments, a control scan with \(^{11}\text{C}\)-LY2459989 alone was followed by a blocking scan either with LY2456302 (34) or with LY2459989 using the triple-tracer method (35). Dose-dependent blockade of KOR and MOR binding by LY2459989 was demonstrated (Fig. 3B). The effective doses to produce 50% receptor occupancy were calculated to be 0.31 and 19.5 mg/kg, respectively, at 20, 40, and 60 min after injection.

PET image reconstruction and definition of regions of interest (ROIs) were the same as described previously (29). Image Analysis and Kinetic Modeling. The procedures for PET image reconstruction and definition of regions of interest (ROIs) were the same as described previously (29). For each scan, radiotracer concentrations over time were measured in 15 ROIs.

Total distribution volume \((V_T, \text{mL/cm}^3)\) was derived by kinetic analysis of the regional time–activity curves, using the metabolite-corrected arterial plasma concentration as the input function, according to a 1-tissue (1T) or 2-tissue (2T)-compartment model as well as the multilinear analysis-1 (MA1) method (35,36). Kinetic parameters \((K_1, k_4, k_2, k_3\) for the 1T model; \(K_1-k_4\) for the 2T model) were derived first. In the 1T model, \(K_1 (\text{mL/min}^{-1} \cdot \text{cm}^{-3})\) and \(k_2 (\text{min}^{-1})\) are the rate constants governing the transfer of the ligand into and out of the brain, respectively. In the 2T model, \(K_1\) and \(k_2\) are the rate constants governing the transfer of the ligand into and out of the nondisplaceable compartment, whereas \(k_3 (\text{min}^{-1})\) and \(k_4 (\text{min}^{-1})\) describe the respective rates of association to and dissociation from the receptors (36). The values of \(V_T\) were calculated from the kinetic parameters as \(K_1/k_2\) in the 1T model and as \((K_1/k_2) 	imes (1+k_3/k_4)\) in the 2T model (36). The Akaike information criterion (AIC) was used to evaluate the optimal model for regional \(V_T\) estimates.

Cerebellar \(V_T (V_T_{\text{CER}})\) was used as an estimate of the nondisplaceable distribution volume to calculate the regional nondisplaceable binding potential \((BP_{ND})\) as \(BP_{ND} = (V_T_{\text{ROC}}-V_T_{\text{CER}})/V_T_{\text{CER}}\) (36). KOR occupancies by naloxone, LY2456302, or LY2459989 were calculated using \(V_T\) values from all 15 ROIs to create occupancy plots according to the method of Cunningham et al. (37).

RESULTS

Chemistry

Both LY2459989 (5, Fig. 1) and its less-active \((R)\)-enantiomer were synthesized in greater than 98% enantiomeric purity. The radiolabeling precursor (6, Fig. 2) was also prepared in greater than 99% chemical purity and greater than 99% enantiomeric purity. Detailed synthetic procedures are described in the supplemental material.

In Vitro Binding Assays and Ex Vivo Evaluation in Rats

LY2459989 displayed high KOR affinity \((K_i = 0.18 \text{nM})\) and more than 43-fold selectivity for KOR over other ORs \((K_i = 7.68 \text{nM}\) for MOR and 91.3 \text{nM}\) for DOR) (supplemental materials).

The potential of LY2459989 as a tracer candidate was assessed in rats using an intravenous dose of 3 \text{μg/kg} and analysis of tissue concentrations by the LC/MS/MS method (38). A rapid initial brain uptake was seen at 5 min after injection. Ligand concentration was higher in the striatum than cerebellum at all time points (Fig. 3A). The striatum–to–cerebellum concentration ratio, as a measure of specific binding, was 2.9, 4.1, and 4.0, respectively, at 20, 40, and 60 min after injection.

In vivo binding at KOR, MOR, and DOR was also assessed with LC/MS/MS after oral administration of ascending doses of LY2459989 using the triple-tracer method (32). Dose-dependent blockade of KOR and MOR binding by LY2459989 was demonstrated (Fig. 3B). The effective doses to produce 50% receptor occupancy were calculated to be 0.31 and 19.5 mg/kg, respectively, for KOR and MOR. These \(ED_{50}\) values translated to a selectivity of approximately 63 folds for KOR over MOR, similar to the selectivity measured in vitro (~43 times; supplemental material and Supplemental Table 1). At the maximum dose administered (30 mg/kg), LY2459989 induced no blockade of DOR binding, consistent with its low affinity for this receptor subtype (Fig. 3B; supplemental material and Supplemental Table 1).

Radiochemistry

Radiosynthesis of \(^{11}\text{C}\)-LY2459989 is depicted in Figure 2. Paladium-catalyzed displacement of the iodo group in the precursor by \(^{11}\text{C}\)-cyanide resulted in the intermediate \(^{11}\text{C}\)-C,T, which, without separation and purification, was reacted with \(\text{H}_2\text{O}_2\) under basic condition to afford the amide \(^{11}\text{C}\)-LY2459989 \((^{11}\text{C}\)-C,T). This 2-step 1-pot radiosynthesis provided \(^{11}\text{C}\)-LY2459989 in greater than 99% enantiomeric purity (Fig. 4). The radiochemical purity of the product was greater than 98%. The radiochemical yield was 7.4% ± 3.8% at the end of synthesis (calculated from trapped \(^{11}\text{C}\)-cyanide and uncorrected for decay), with a specific activity of 22.6 ± 0.9 GBq/μmol (end of synthesis, \(n = 16\)). Total synthesis time was 40 ± 5 min.

FIGURE 2. Radiosynthesis of \(^{11}\text{C}\)-LY2459989. Reagents and conditions: a, \(\text{H}^\ast\text{CN}, \text{KHCO}_3, \text{Pd}_2(dba)_3, \text{dpf}, \text{DMF}, 80^\circ\text{C}, 5 \text{~min}\); b, \(\text{NaOH}, \text{H}_2\text{O}_2, 80^\circ\text{C}, 5 \text{~min}\).
In Vivo Evaluation in Rhesus Monkeys

After a bolus injection of $^{11}$C-LY2459989 ($140.6 \pm 45.5$ MBq; specific activity, $12.2 \pm 4.7$ GBq/μmol at time of injection; injected mass, $4.8 \pm 0.7$ μg, $n = 12$) into a rhesus monkey, total activity and parent activity in the plasma exhibited a rapid rise and clearance phase and then either stabilized or decreased slowly over time (Fig. 5A). At 30 min after tracer injection, parent fraction was approximately 25%, indicating a fairly rapid metabolism of the radioligand (Fig. 5B). The plasma-free fraction of $^{11}$C-LY2459989 was about 4.6%, compared with less than 1% for $^{11}$C-LY2795050 (29).

In the rhesus monkey brain, $^{11}$C-LY2459989 displayed good uptake and a heterogeneous distribution pattern (Fig. 6A). The nonselective opioid antagonist naloxone at a dose of 1 mg/kg reduced $^{11}$C-LY2459989 uptake in all brain regions to nearly homogeneous levels (Fig. 6B), an effect similarly induced by 0.3 mg/kg of the selective KOR antagonist LY2456302 (Fig. 6C).

Time–activity curves of $^{11}$C-LY2459989 in selected brain regions are presented in Figure 7. Higher uptake was seen in the globus pallidus, cingulate cortex, insula, caudate, and putamen; lower in the frontal cortex and thalamus; and lowest in the cerebellum (Fig. 7A). Regional activity in the brain typically reached peak levels within 10–20 min after tracer injection, indicating fast uptake kinetics. When naloxone was given before $^{11}$C-LY2459989, time–activity curves in higher binding regions trended down to the same level as that in the cerebellum (Fig. 7B). Furthermore, regional uptake of $^{11}$C-LY2459989 was also markedly reduced by pretreatment with LY2456302 (0.3 mg/kg, Fig. 7C).

Regional time–activity curves were analyzed with 1T and 2T compartment models (36) and the MA1 method (35) using the metabolite-corrected plasma input function. The 2T model was...
Table 1. Listed in Table 1 are MA1-derived $V_T$ values. Regional values of nondisplaceable binding potential ($BP_{ND}$), as a measure of specific binding signal, were calculated using the cerebellum as the reference region (Table 2). In the baseline scans, MA1-derived $V_T$ or $BP_{ND}$ values followed the order of globus pallidus > cingulate cortex > insula ~ caudate ~ putamen > frontal cortex ~ temporal cortex ~ thalamus > cerebellum. When the monkeys were pre-
treated with naloxone (1 mg/kg), LY2456302 (0.3 mg/kg), or un-
labeled LY2459989 (36 μg/kg), the specific binding of
$^{11}$C-LY2459989 was significantly blocked, as reflected by the neg-
ligible $BP_{ND}$ values in most brain regions. On the basis of the oc-
cupancy plot analysis of the MA1-derived $V_T$ values (37), 91% ±
2% of KOR was occupied by 1 mg/kg of naloxone in 2 monkeys.
KOR occupancies of 77% and 93%, respectively, were induced by 0.03 and 0.3 mg/kg of LY2456302, whereas an occupancy of 72% ±
5% was achieved in the self-blocking experiments with 36 μg/kg of
$^{11}$C-LY2459989 in 2 separate monkeys.

**FIGURE 6.** PET images of $^{11}$C-LY2459989 in transaxial (left), coronal (middle), and sagittal (right) views from baseline (A) and blocking scans with 1 mg/kg of naloxone (B) or 0.3 mg/kg of LY2456302 (C). Images are summed from 30 to 45 min after $^{11}$C-LY2459989 injection and presented in standardized uptake value unit.

**DISCUSSION**

In this paper, we describe the synthesis and evaluation of $^{11}$C-
LY2459989 as an improved antagonist radiotracer for PET imaging of
KOR in rhesus monkeys. $^{11}$C-LY2459989 is a fluorine-containing an-
alog of $^{11}$C-LY2795050, a first antagonist tracer developed at our laboratory and shown to be suitable for in vivo imaging and quantification of KOR in nonhuman primates (29). $^{11}$C-LY2459989 was synthesized in a route similar to that for LY2795050 (30). In radioligand competition assays in vitro, $^{11}$C-LY2459989 displayed high KOR binding affinity ($K_i = 0.18 \text{ nM}$) and more than 43-fold selectivity for KOR over other ORs ($K_i = 7.68 \text{ nM}$ for MOR and 91.3 nM for DOR). Compared with LY2795050 ($K_i = 0.72 \text{ nM}$ for KOR), $^{11}$C-LY2459989 exhibited 4-times-higher KOR affinity and similar selectivity. Given this favorable in vitro binding profile, ex vivo evaluation was performed in rodents to assess its potential as a tracer candidate.

$^{11}$C-LY2459989 was administered intravenously to rats at a dose of 3 μg/kg. This dose was selected to be low enough to approximate tracer conditions while allowing the accurate measurement of tissue concentrations by LC/MS/MS analysis (32). $^{11}$C-LY2459989 was found to have excellent brain penetration, with initial uptake levels of 24.7 and 14.4 ng/g in the striatum and cerebellum at 5 min after injection, which were more than 6 times higher than those of LY2795050 (4.0 and 2.0 ng/g) (29). Specific binding of $^{11}$C-LY2459989 was also higher, with striatum-to-cerebellum ratios of 4.1 and 4.0 at 40 and 60 min after injection, respectively, versus 2.2 and 3.3 for LY2795050 (29).

Receptor occupancies at the rat KOR, MOR, and DOR were also assessed with LC/MS/MS after oral administration of ascending doses of LY2459989 using the triple-tracer method, with intravenous injection of GR103545 (1.5 μg/kg), naltrexone (10 μg/kg), and naltriben (10 μg/kg) as tracers for measuring binding to KOR, MOR, and DOR (32). KOR and MOR binding was re-
duced by $^{11}$C-LY2459989 in a dose-dependent manner. From the saturation curves, the $^{11}$C-LY2459989 $ED_{50}$ was calculated to be 0.31 mg/kg for KOR and 19.5 mg/kg for MOR, which corresponded to about 63-fold KOR/MOR selectivity in vivo, consistent with the approximate 43-times KOR/MOR selectivity measured in vitro.

The radiolabeled ligand $^{11}$C-LY2459989 was prepared in high radiochemical purity in a 2-step radiosynthetic pathway using $^{11}$C-HCN as the radiolabeling agent. The re-
action conditions used in the radiosynthesis

**FIGURE 7.** Time-activity curves in selected brain regions from $^{11}$C-LY2459989 baseline scan (A) and blocking scans after naloxone (B), 0.3 mg/kg of LY2456302 (C), or 36 μg/kg of $^{11}$C-LY2459989 (D).
did not lead to any racemization of the chiral structure and thus resulted in high enantiomeric purity (>99%) of the product.

PET imaging experiments in rhesus monkeys indicated a fairly rapid rate of metabolism for 11C-LY2459989, with approximately 25% of parent tracer remaining in the plasma at 30 min after injection. Similarly, fast uptake kinetics were detected in the monkey brain, with peak uptake times within 10–20 min after tracer administration. The distribution of 11C-LY2459989 was consistent with the brain, with peak uptake times within 10–20 min after injection. Because of the higher KOR binding affinity, specific binding of 11C-LY2459989 is much higher, with regional BPND values more than twice of those for 11C-LY2795050 in the monkey brain (Table 2).

**CONCLUSION**

In this report, we demonstrate that the novel radioligand 11C-LY2459989 exhibits a favorable metabolic profile, brain uptake kinetics appropriate for a 11C tracer, and high regional specific binding signals in rhesus monkeys. Hence, 11C-LY2459989 represents a much improved radiotracer for PET imaging and quantification of KOR in vivo.
